# 1 Background

The B-Safe r-shiny application is an interactive statistical software used to analyse several safety endpoints using the Bayesian (robust) Meta-Analytic Predictive (MAP) method. This approach was based on the works of [1].

## 1.1 Requirement Specification

The application will present its results via graphs, tables and figures. The application will calculate the meta-analytic predictive (MAP) prior and the robust MAP priors, assesses prior data conflict and reports the effective sample size / effective number of events of the historical data.

The user will then be able to download output data / simulated results in a tabular form.

An error message is expected when the input table does not contain the required columns and when the input parameters does not match the intended analysis.

## 1.2 Purpose and Scope

The aim of this testing and validation plan is to test whether the application is working as specified and that all described functionality are working as intended.

Test cases will cover common use cases of the application with the aim of ensuring that calculations done by the application are implemented properly. If there are any computations that cannot be performed by the application, additional changes or modifications to the application will be done in the future. That is beyond the scope of this document.

# 2 Testing and Requirement Strategy

Software and packages used by the application to perform the validation includes:

Table 1: Softwares and Packages

Program	Version
R	
RStudio	
shiny	1.7.5.1
RBesT	1.7.2
Rmarkdown	2.25
R2jags	0.7-1
rstantools	2.1.1
bayesplot	1.8.1
checkmate	2.3.1
testthat	3.2.1

The testing strategy is based on Input Testing and Structural Testing. Input Testing is performed to investigate whether erroneous input by the user is handled as intended by the application. Structural Testing deals with the confirmation of the accuracy of the calculations done by the application. Different scenarios to cater for common cases will be simulated for the structural testing to be performed.

# 3 Input Testing

This section describes the verification procedure of the functionality of the B-Safe application.

First, testing requirements and strategies are outlined. Then the handling of the testing failures and the processes for performing the testing are characterized.

The table below gives a brief overview about the parameters/variables the user is able to set as used within the document.

Table 2: Definitions of Variable

Variable	Description
STUDYID	Study number or name
HIST	0 for current trial and 1 for historical trial
ARM	Defines the treatment arm of the analysis
SAF_TOPIC	Safety topics of interest
N	Total number of patients in the respective study
N_WITH_AE	Total number of patients for the respective safety topic in that study who experienced at least one adverse event
TOT_EXP	Total exposure time for the respective safety topic in that study: sum of patients treatment exposure period until occurrence of first event. If no event occurs, use complete observation time
Dose	Amount/weight of the drug the patient took
Freq	Number of times the medicine/drug was taken by the patient
Length	Time the patient was on the treatment
Treat	The specific treatment the patient was on
MAP Prior	Meta-Analytic Predictive Prior
CrI	Credible Interval
CrILB	Credible Interval Lower Boundary
CrIUB	Credible Interval Upper Boundary
ESS	Expected Sample Size
ENE	Expected Number of Events

In case the expected specifications are not met, the test is failed.

The conditions above are all implementations that needs to be tested before the actual testing of the full functionality of the B-Safe application can be executed. Various test cases are grouped together and performed in a single action. For example, all test cases that contain checking the applications handling of input values/characters.

All those requirements are testest via the *checkmate* R package, which allows for both warnings as well as errors to guide the user along the error and help fixing the problem. In addition the required variables are within the same approach not only tested for specific required typing, but also the *checkmate* R package allows to test certain boundaries of those variables as well as restricting inputs to certain formats, e.g., csv.

### 3.1 Binary Endpoint

1. Setup a .csv file

Assumptions of the variables:

Table 3: Input

Input	Specification
File type	.csv file
STUDYID	character or numeric variable
HIST	boolean character variable

ARM	character variable
N	integer/numeric variable greater than zero
SAF_TOPIC	character variable with less than 30 characters
N_WITH_AE	integer variable greater than zero but less or equal to N
TOT_EXP	numeric variable greater than zero
Dose	numeric variable that can be treated as a factor. It is an additional variable
Freq(Frequency)	integer variable that can be treated as a factor. It is an additional variable
Length	a numeric variable that is an additional factor

Robust MAP Prior:

2. Weakly-informative Prior weight is numeric between 0.01 and 0.99

New Trial Analysis:

3. Number of Patients in selected ARM is an integer  $> 0$  but  $\leq 200$
4. Number of Patients with with AE is an integer  $\geq 0$  but  $\leq$  number of patients in selected ARM

Decision Making:

5. Likelihood: Percentage of Patients with AE two integers specifying lower bound and upper bound from 0 to 100.
6. MAP Prior: Percentage of Patients with AE two integers specifying lower bound and upper bound from 0 to 100.
7. Robust MAP Prior: Percentage of Patients with AE two integers specifying lower bound and upper bound from 0 to 100.
8. Posterior: Percentage of Patients with AE two integers specifying lower bound and upper bound from 0 to 100.

Download Results:

9. Number of comparisons: integer from 1 to 5

Test cases were performed as shown in the the table below. Different formats of the various input are violated in different test cases. For any false input, the user shall be informed about the error and the error will be displayed. The test is passed if no error message is displayed.

Test Case	Description of violation	Expected Response	Observed Response
1	An xlsx file uploaded	Error	Error
2	A file without the StudyID coulum uploaded	Error	Error
3	A file without the Hist coulum uploaded	Error	Error
4	A file without the ARM column uploaded	Error	Error
5	A file without N column uploaded	Error	Error
6	A file without N_WITH_AE uploaded	Error	Error
7	A file without SAF_Topic uploaded	Error	Error
8	A file without Dose column uploaded	No Error	No Error
9	A file without FREQ column uploaded	No Error	No Error
10	A file without Length coumn uploaded	No Error	No Error
11	A file with number of Patients less than zero	Error	Error
12	A file with more events patients	Error	Error

Some inputs including weakly-informative prior weight for the calculation of Robust MAP Prior, number of patients in selected arm and number of patients with AE in the new trial analysis, percentages for making statistical inferences about MAP Prior, Robust MAP Prior, Likelihood and Posterior are all imputed with a slider. Different values along the range on the sliders will be tested in the various scenarios.

### 3.2 Time To Event Endpoint

1. Setup a .csv file

Assumptions of the variables:

Table 4: Input

Input	Specification
File type	.csv file
STUDYID	character or numeric variable
HIST	boolean character variable
ARM	character variable
N	integer/numeric variable greater than zero
SAF_TOPIC	character variable with less than 30 characters
N_WITH_AE	integer variable greater than zero but less or equal to N
TOT_EXP	numeric variable greater than zero
Dose	numeric variable that can be treated as a factor. It is an additional variable
Freq(Frequency)	integer variable that can be treated as a factor. It is an additional variable
Length	a numeric variable that is an additional factor

Robust MAP Prior:

2. Weakly-informative Prior weight is numeric between 0.01 and 0.99
3. Weakly-informative Prior mean on the exp scale is numeric between 0.01 and 3

New Trial Analysis:

4. Number of first occurrence of the event is numeric between 1 and 200
5. Cumulative time to occurrence of the first events is numeric between 1 and 1000

Decision Making:

6. Likelihood: area of log(hazard) for patients with AE is numeric within a 99.8% (0.01% to 99.9%) quantile.
7. MAP Prior: area of log(hazard) for patients with AE is numeric within a 99.8% (0.01% to 99.9%) quantile.
8. Robust MAP Prior: area of log(hazard) for patients with AE is within a 99.8% (0.01% to 99.9%) quantile.
9. Posterior: area of log(hazard) for patients with AE is numeric within a 99.8% (0.01% to 99.9%) quantile.

Download Results:

10. Number of comparisons: integer from 1 to 5

Test Case	Description of violation	Expected Response	Observed Response
1	An xlsx file uploaded	Error	Error
2	A file without the StudyID column uploaded	Error	Error
3	A file without the Hist column uploaded	Error	Error
4	A file without the ARM column uploaded	Error	Error
5	A file without N column uploaded	Error	Error
6	A file without N_WITH_AE uploaded	Error	Error
7	A file without TOT_Exp uploaded	Error	Error
8	A file without SAF_Topic uploaded	Error	Error
9	A file without Dose column uploaded	No Error	No Error

10	A file without <code>FREQ</code> column uploaded	No Error	No Error
11	A file without <code>Length</code> column uploaded	No Error	No Error
12	A file with number of patients less than zero	Error	Error
13	A file with more events than patients	Error	Error
14	A file with a negative <code>TOT_Exp</code> uploaded	Error	Error

---

Some inputs including weakly-informative prior weight for the calculation of Robust MAP Prior, number of patients in selected arm and number of patients with AE in the new trial analysis, percentages for making statistical inferences about MAP Prior, Robust MAP Prior, Likelihood and Posterior are all imputed with a slider. Different values along the range on the sliders will be tested in the various scenarios.

## 4 Testing Framework in `testthat`

For testing purpose with `testthat`, the values for the defined scenarios, were created beforehand and saved as a separate file. As well were reference images for scenario 03 created and saved for comparison. Moreover, due to the use of Stan, also for image comparison the `RBest gMAP` element was saved. Moreover, the parameter, used in testing, were also defined upfront and are saved in the same file `tests/testthat/thresholds`.

Therefore the `testthat` R package is being used to ensure a framework, that is commonly used and stable.

Hereby, the testing setup replicates partially the workflow of the application with loading the respective data, parameters as well as thresholds. Then all functions that B-SAFE is running are run in the needed order to ensure the same workflow. Afterwards the outputs of the different plots as well as tables that are being displayed within the application are compared against the reference images, where the binaries of the images are compared and expected to be equal. Regarding the tables, the thresholds, both for the lower as well as the upper limits are being used to create threshold tables which then the corresponding tables / values of the replicated application workflow are compared against. The framework then either passes the comparison as the values are within a certain tolerance, or the framework will throw an error when the values are not within the threshold respective their tolerance.

In the setup file (`tests/testthat/setup.R`), all plots will be created and saved in (`tests/testthat/test_img`). This will be executed, prior to the pixel wise comparison. Here all plots will be created. Then in (`tests/testthat/tests-plots.R`) all the different created plot images will be binary tested against the reference images (`tests/testthat/img`) to ensure reproducibility.

ESS and summary statistics are tested independently from each other, for reason see section 5.1.

Moreover the displayed tables are checked, that the values and NA's are at their correct position. If a row (e.g. MAP prior summary statistics) appears in two different displayed tables, we check that they are identical.

Further unit tests have been created to ensure the correct functionality for the helper functions. The overall test coverage is greater than 80%.

## 5 Scenario Testing

Scenario testing was used to verify the computations the B-Safe Shiny application performs.

For this purpose, various conditions were set to capture a wide array of possibilities to set different parameter values. Each simulated scenario is a representation of a probable occurrence in a clinical trial. There are scenarios to cover heterogeneous and homogeneous data, very large to small borrowing of historical information, high and low robustification of the MAP prior. These scenarios are tested for both the Adverse Event Incidence Proportion and the Exposure-Adjusted Adverse Event Rate.

Following each scenario is briefly described. The simulated data sets are displayed in section 5.1. For further information (e.g. the level of heterogeneity) please refer to the statistical analysis plan of B-Safe.

## 5.1 Simulation and Testing of Scenarios

In this chapter, the scenarios that are described in section 6 for incidence proportions and in section 7 for exposure adjusted incidence rates respectively, will be simulated and run through the B-SAFE app with the results being cross-checked for errors.

The testing procedure is as follows. The fixed historical data for each scenario as shown in their respective sections above, were run through `RBest` 1000 times to generate a set of 1000 different MAP / robust MAP priors. From this set of MAP / robust MAP priors, upper and lower thresholds for the following summary statistics were calculated by taking the 1% and 99% quantile of the summary statistics that were observed over the 1000 simulation replicates. Summary statistics for the MAP / robust MAP priors were: mean, SD, median, 95% Credible Intervals, ESS.

Each of the 1000 MAP / robust MAP priors for each scenario was subsequently updated with the corresponding (fixed) new trial data for that scenario, where the new data is as shown in the tables. Summary statistics for the likelihoods and the posterior distributions were again calculated, and upper and lower thresholds determined as above. The code can be found under `tests/teststrat/ScriptThresholds.R`.

Tests are then run using `testthat`. A test will pass if the summary statistics (for the MAP prior, robust MAP prior, likelihood, and posterior) lie within the upper and lower thresholds with a respective tolerance, and fail otherwise. The tolerances were included to adjust for the variability in results. Due to the use of `stan` within `RBest` on each machine a different MCMC is the result of the function calls. For good scenarios (e.g. 1,3) this threshold could be very small (e.g.  $1 \cdot 10^{-4}$ ). For worse scenarios (e.g. 4,5), the variability is higher. We decided to use one tolerance for the binary (e.g.  $3 \cdot 10^{-2}$ ) and another for the time to event endpoint (e.g.  $8 \cdot 10^{-2}$ ). We used the highest rounded difference we encountered during a couple of test runs.

For the ESS/ENE we decided for a 10% tolerance. However, as seen by the observed minimum and maximum values of the 1000 runs, in some cases a absurdly high ESS/ENE is reported. This is a known `RBest` issue, and we have contacted the authors. For certain mixture components with especially low weights, the integration function malfunctions. Therefore, if the ESS/ENE exceeds the number of patients/events, the MCMC sample will be drawn again, up to three times. After a third attempt the test will fail.

Moreover, for certain scenarios (2, 4, 12), this issue leads to the general exclusion to test these scenarios. In general those are scenarios in which borrowing historical information is strongly discouraged to perform.

Some values are not displayed, neither in the exploratory nor the reporting feature of B-SAFE. Nevertheless, for coding reasons, they are still part of the array structure and will be mentioned here as not available (NA).

## 5.2 Code der Daten Simulation

The scripts generates synthetic data that mimics real-world studies. The code can also be found under `tests/teststrat/SimStudy.R`

```
# Function to simulate 1 study
# nPat = Number of patients in each group
# g1 = group 1 (treatment); g2 = group 2 (control)
# dropout = 0_05: 5% dropout after time units of measure
# accr = accrual time, is to be in regards to the hazard
# NObsEvt = type 2 censoring, censor after NObsEvt number of events, probability of observing the event
# accr_timepoint should include 0 and total accrual time_
# Pre-specify the censor type ahead of time

#' Simulate a study
#'
#' @param nPat
#' @param hz
#' @param dropout
```

```

## 6.12 Scenario 12 - Continued study duration with Worst Setting

Scenario 12 describes a binary endpoint for a scenario with a worst case scenario (scenario 4) that continued till the end of the proposed study duration. The scenario characteristics includes huge censoring, huge noise, little events observed, heterogeneous historical and huge prior data conflict.

```

SimTestData(
  SimStudy_nPat = c(g1 = 200, g2 = 200),

## 7.2 Scenario 2 - Strong Prior Data Conflict

Scenario 2 describes a test case scenario for a binary endpoint with a strong prior data conflict between the historical and current trials. The characteristics of this scenario includes no censoring in the current trial, no noise, all events being observed, homogeneous historical data and heavy prior data conflict.

```
# Scen2

### 7.3 Scenario 3 - Realistic Scenario

Scenario 3 describes a binary endpoint for a realistic situation with a dropout rate of 5%, some with a 2% tau, events observed at a 90% power, homogeneous historical data and with no planned prior data conflict.

```
SimTestData(
  SimStudy_nPat = c(g1 = 200, g2 = 200),
  SimStudy_hz = c(g1 = 0.1, g2 = 0.2),
  SimStudy_dropout = c(rate = 0.05, time = 12),
  SimStudy_accr = 6,
  SimStudy_accr_method = "Uniform",
  SimStudy_surv_method = "Exponential",
  SimStudy_intensity = NA,
  SimStudy_accr_timepoint = NA,
  SimStudy_time_cutoff = 18,
  SimStudy_NObsEvt = 93,
  SimStudy_censor_type = 2,
  nStudy = 6,
  tau = 0.02,
  prior_data_conflict = FALSE,
  pdc_hz = NA,
  SAF_TOPIC = "Scen3",
  seed = 1701621384
)
```

## 7.11 Scenario 11 - Continued study duration with Realistic Setting

Scenario 11 describes a binary endpoint for a realistic situation where the study continued regardless of when the proposed number of events has been observed. Characteristics of this scenario includes a drop out rate of 5%, noise at a 5% tau, homogeneous historical data and no planned prior data conflict planned.

```

## 7.12 Scenario 12 - Continued study duration with Worst Setting

Scenario 12 describes a binary endpoint for a scenario with a worst case scenario (scenario 4) that continued till the end of the proposed study duration. The scenario characteristics includes huge censoring, huge noise, little events observed, heterogeneous historical and huge prior data conflict.

```
SimTestData(
  SimStudy_nPat = c(g1 = 200, g2 = 200),
